Urban
Initiative**

Outline

- ❖ Introduction: Urban flood in changing context
- ❖ Flood inundation modeling
- ❖ Climate projections downscaling and adaptation

Introduction

- ▶ Flooding occurs frequently in Jakarta during the rainy season, causing huge losses.
- ▶ Flooding (due to heavy rainfall and overflowing of river water) is identified as a significant risk for conception and transmission of water-borne illness (e.g., diarrhea).
- ▶ Flood simulation under changing scenario is required for the human health risk assessment of the flood-affected population.

<http://contemporarycity.org/2014/04/jakarta/>

Urban expansion in Greater Jakarta

Climate change

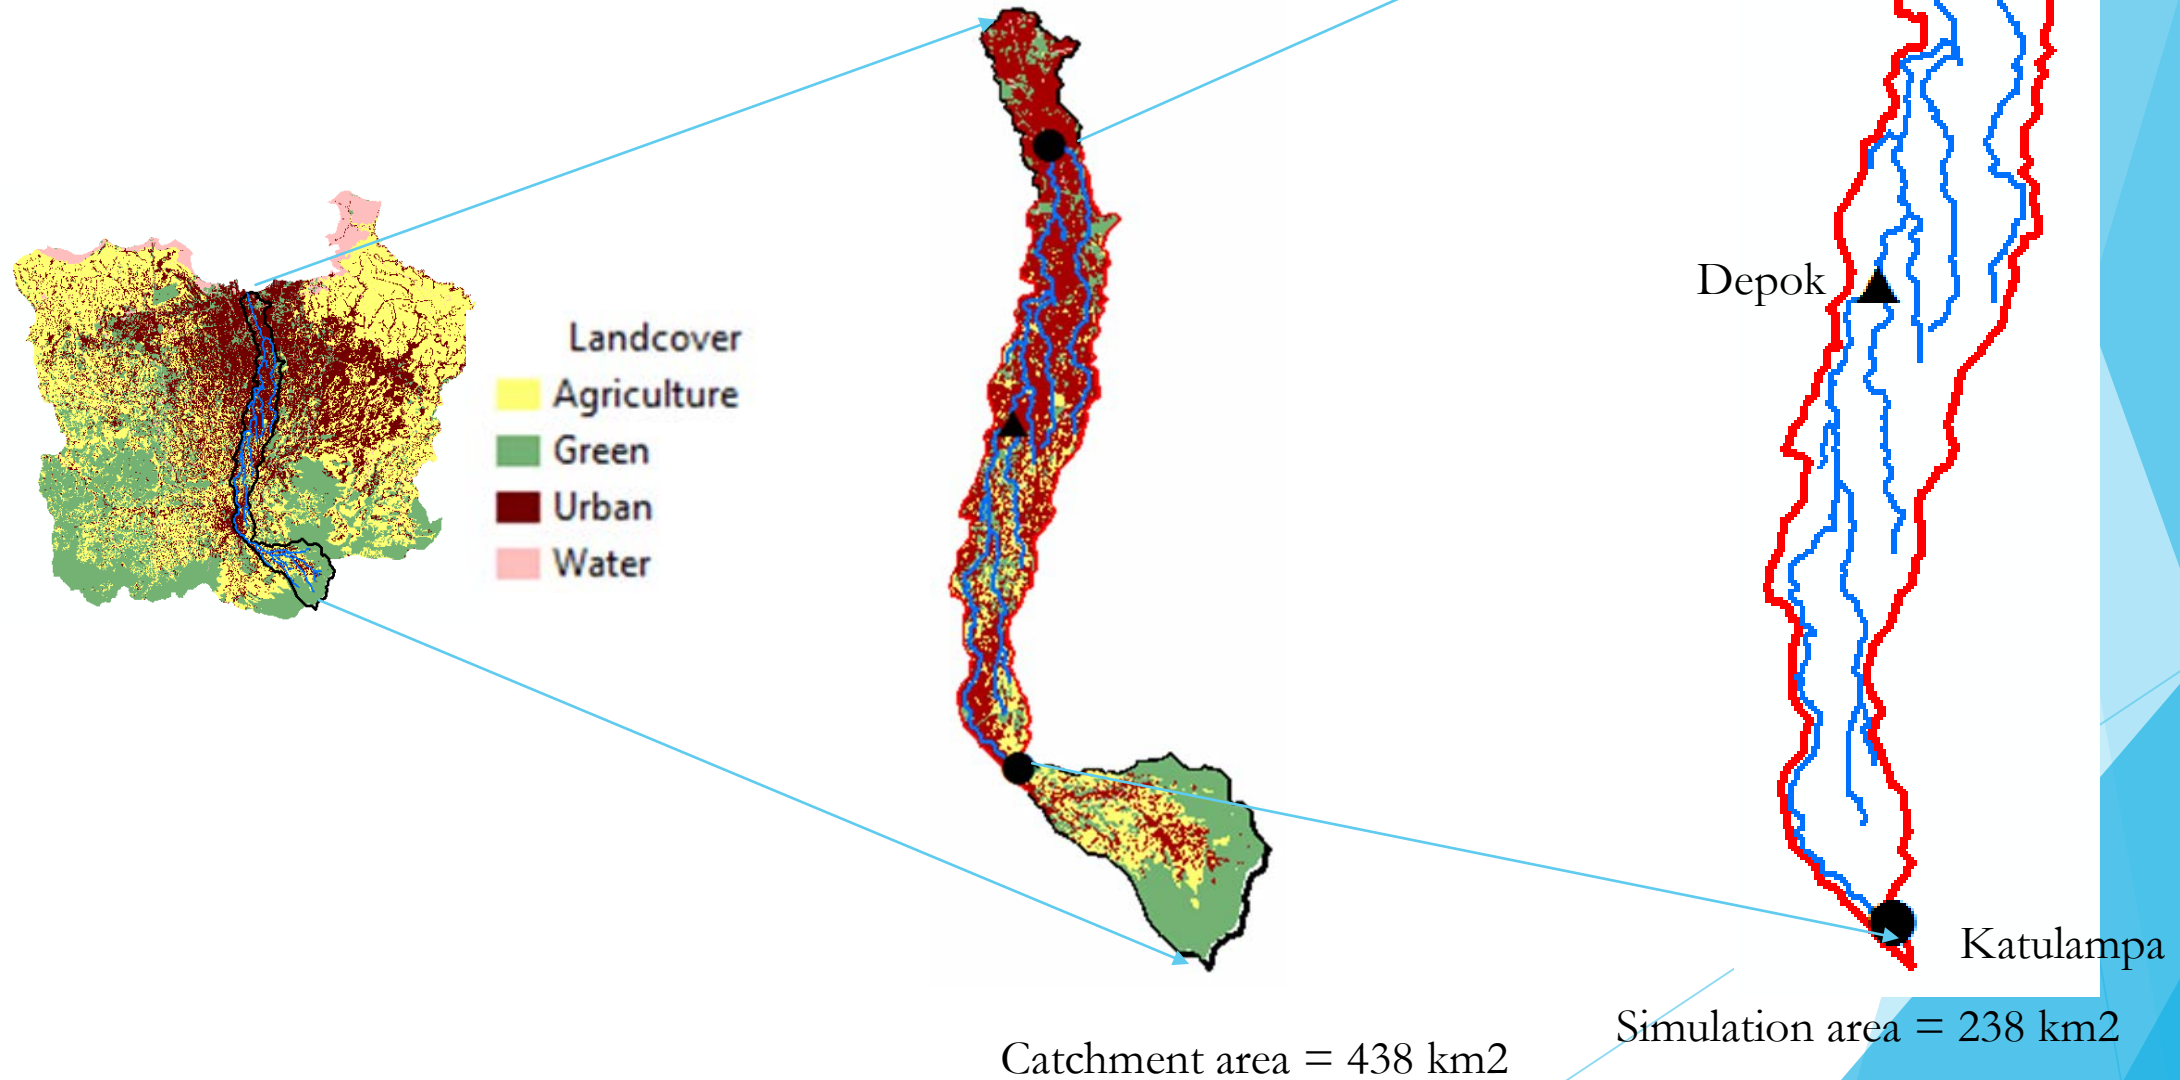

- ▶ Climate change exacerbates the frequency and intensity of hydro-meteorological disasters
- ▶ The incidence of extreme precipitation events is expected to increase, resulting frequent intense flood disasters

Modeling area: Ciliwung river basin

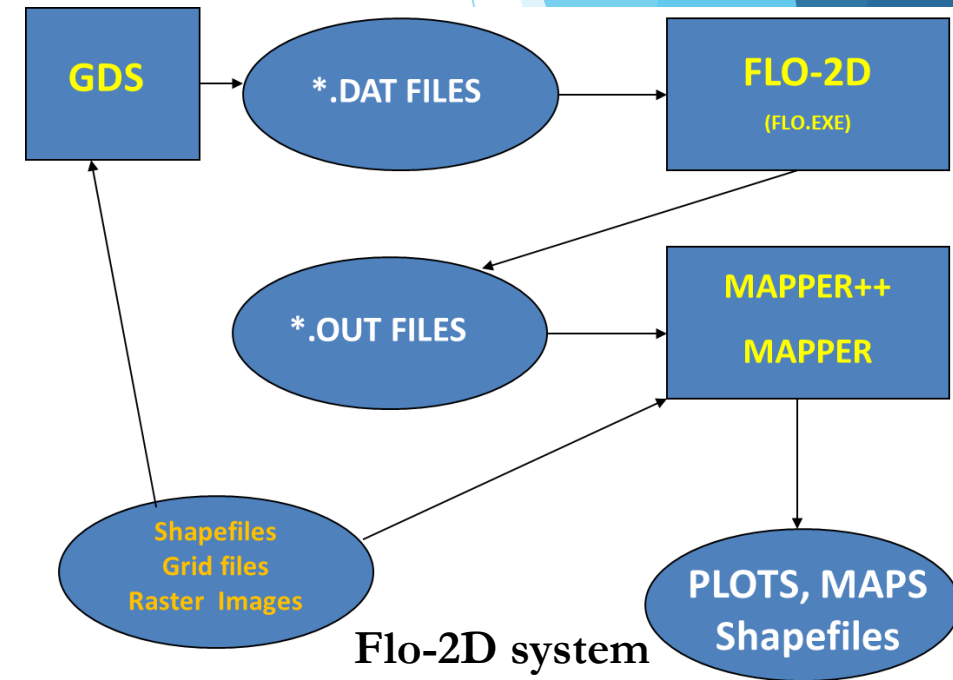

- ▶ High flow rates in the Ciliwung River flowing through Jakarta regularly causes extensive flooding in the rainy season.
- ▶ Inundation occurs because of the Ciliwung River overflowing when it is unable to accommodate flood discharge from upstream.
- ▶ The case study area encompasses the floodplain along the Ciliwung River from upstream of Manggarai Gate to Katulampa hydrological station.
- ▶ The case study area comprises dense population, rapid urbanization and flood-prone locations in Greater Jakarta.

Modeling area: Ciliwung river basin

Inundation model set-up

- ▶ This study uses Flo-2D, a two-dimensional hydrologic-hydraulic model, to analyze characteristics (area, depth, time of occurrence, flow velocity) of urban flooding.
- ▶ A flood event of February 2007 was used for the inundation model set-up.
- ▶ River network and floodplain delineation is based on SRTM 90 m elevation data.
- ▶ Daily inflow (discharge) and rainfall at Katulampa and Depok stations respectively were used for the model set-up.
- ▶ Urban stormwater flow is governed by natural flow (due to lack of pipe network data)

Input data

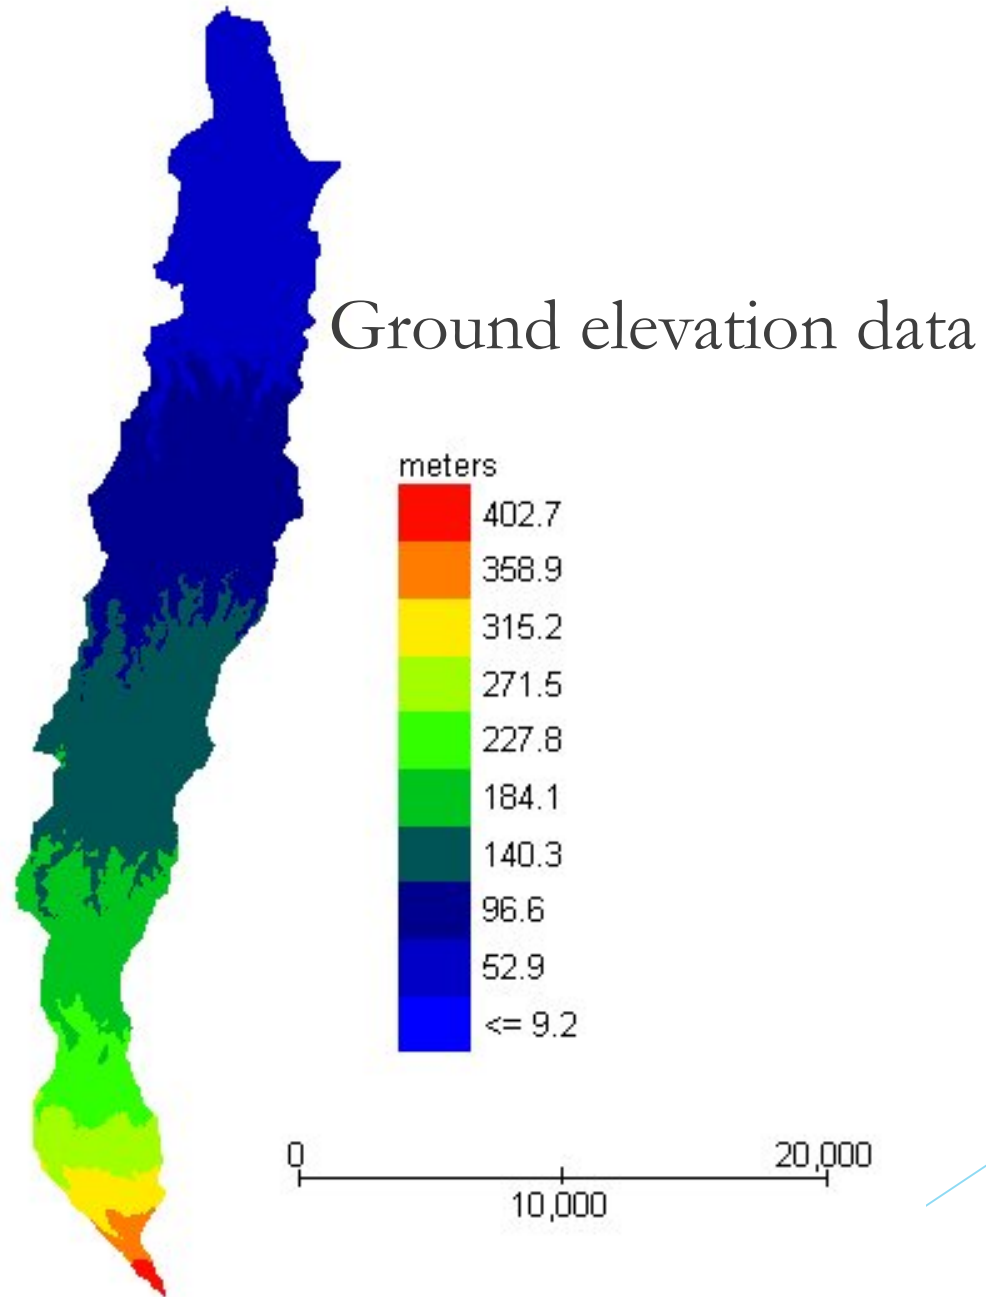

Inflow at Katulampa station

Rainfall at Depok station

Input data

Model Calibration/validation

- ▶ Reference data for the calibration were flood value passing at Ratu Jaya section of Ciliwung river.
- ▶ Observation flood at Ratu Jaya on 3rd February, 2007 was used for calibrating model parameters
- ▶ The most sensitive model parameter was the Manning's roughness
- ▶ Based on the modeling results, the inundation is mapped onto detailed topographic maps.
- ▶ The inundation map will be verified using the data of the inundation area and depths from secondary data and survey.

Results

Area of inundation

Maximum flow depths

Climate projections

- ▶ Climate projections are widely employed to understand the likely impact of climate change.
- ▶ Global climate models (GCM) simulate the response of greenhouse gas concentrations, and provide estimates of climate variables such as temperature, precipitation etc.
- ▶ Climate projections derived from GCM consists of biases, and hence not suitable for direct use at regional/local climate change studies.
- ▶ Downscaling is the process of deriving finer resolution (i.e., regional/local) climate data from GCM climate data.

Climate projections downscaling

Large Scale

± 50 km; weekly - daily

± 25 km; daily

river catchment; hourly

Hydrological scale

Methods

- ▶ Dynamical
- ▶ Statistical

Types

- ▶ Spatial
- ▶ Temporal

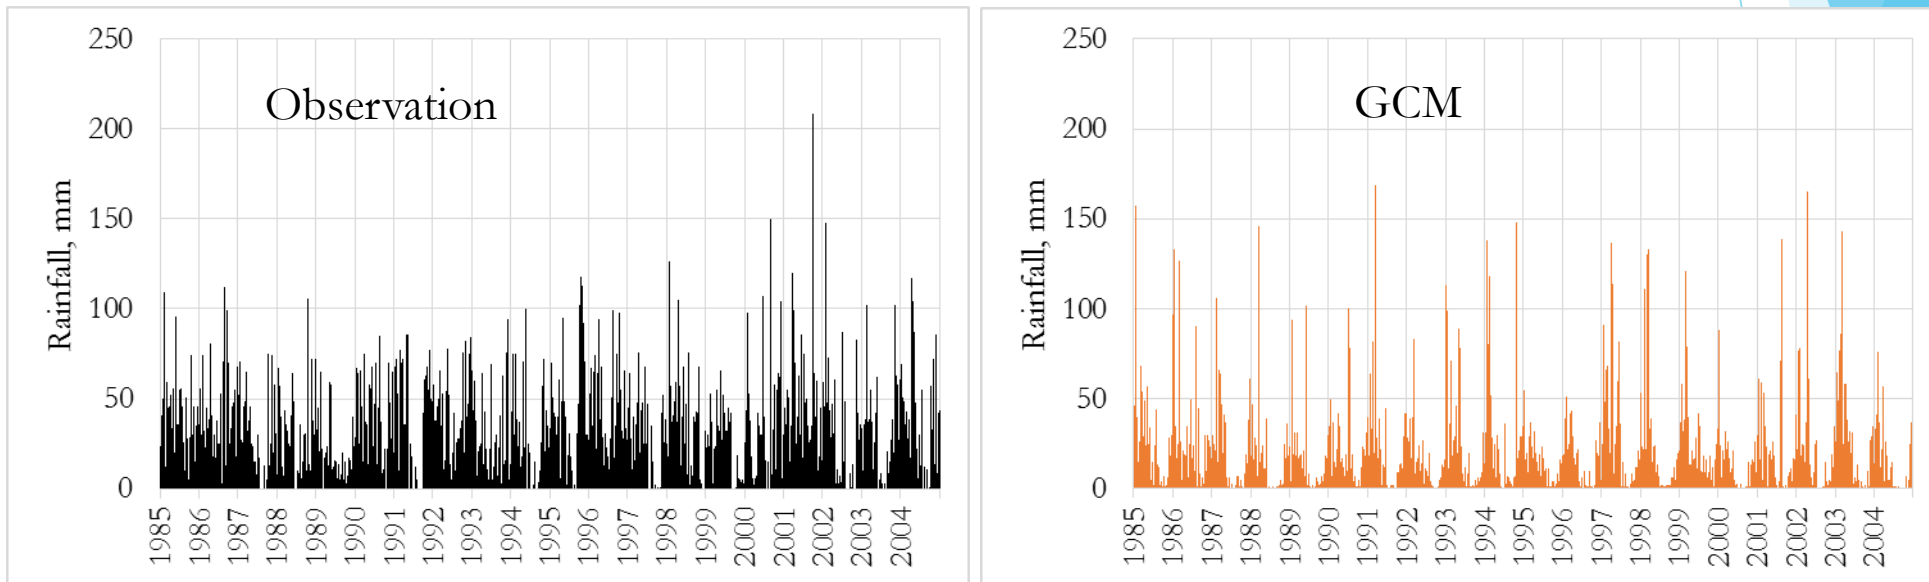

Climate data: MRI-CGCM3

- ▶ MRI-CGCM3 is composed of atmosphere-land, aerosol, and ocean-ice models
- ▶ Horizontal resolution: 120 km
- ▶ Temporal resolution: daily
- ▶ RCP 4.5 and 8.5 were used as the future scenario to obtain future precipitation from MRI-CGCM3
- ▶ Download:

<http://cera-www.dkrz.de/WDCC/ui/Entry.jsp?acronym=MRMC>

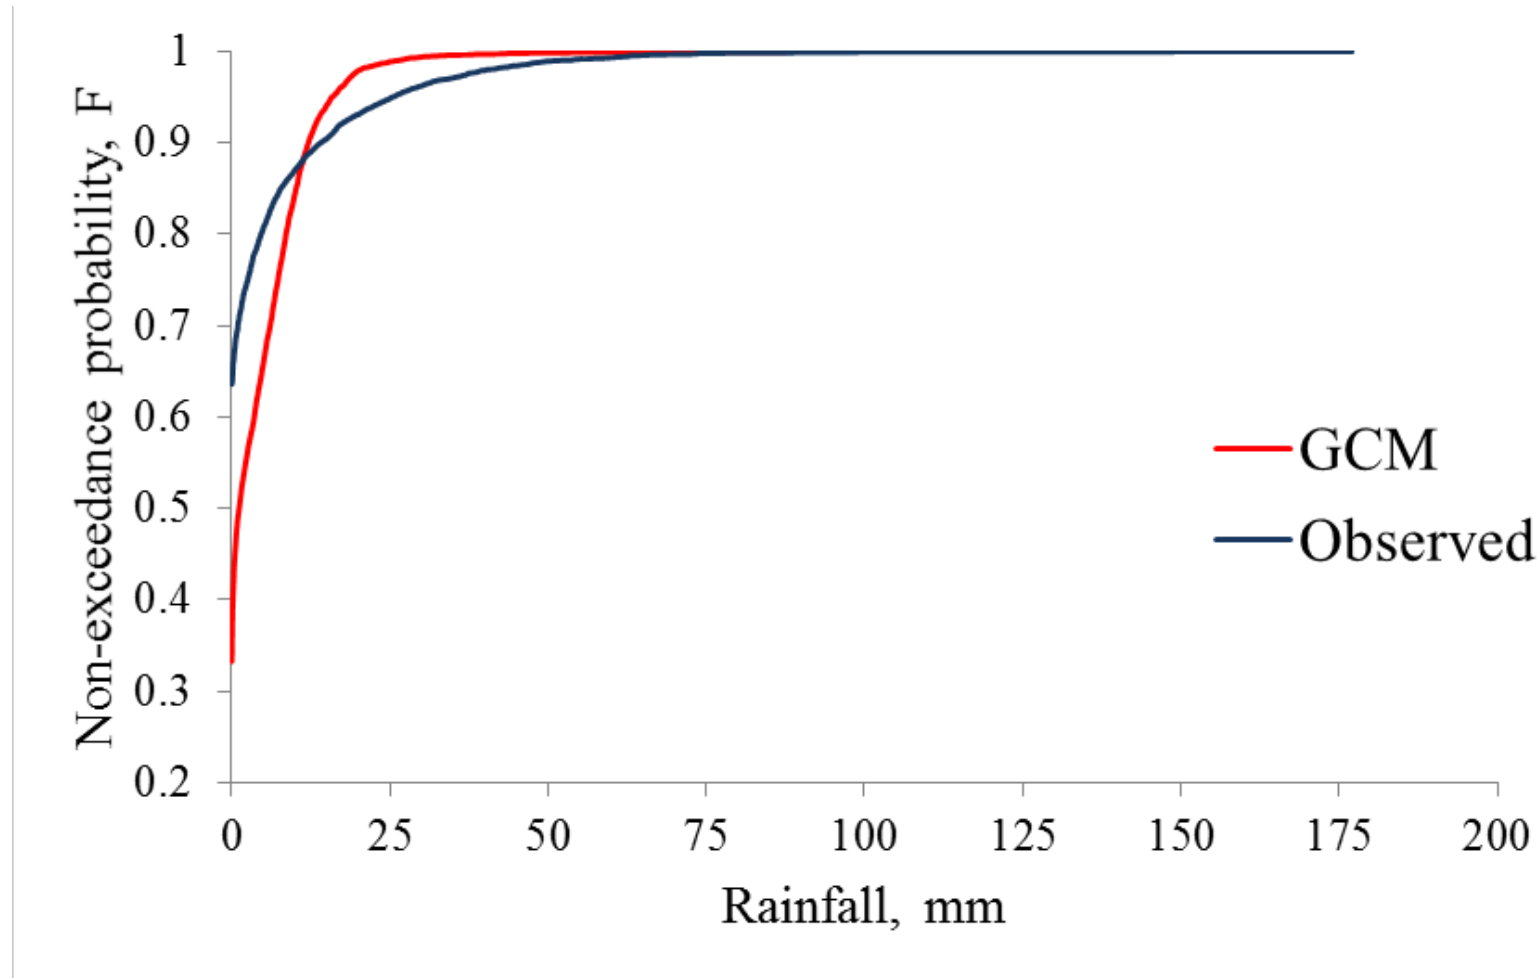

Bias identification

Comparison of observation and MRI-GCM daily rainfall over Jakarta

- ▶ Bias in frequency (too many rainy days for GCM data)
- ▶ Bias in intensity (largely underestimated rainfall for GCM data)

Bias correction (frequency)

Bias correction (intensity)

$$x_{GCM_{Present_corrected}} = F_{obs}^{-1} (F_{GCM_{Present}} (x_{GCM_{20_{Present}}}))$$

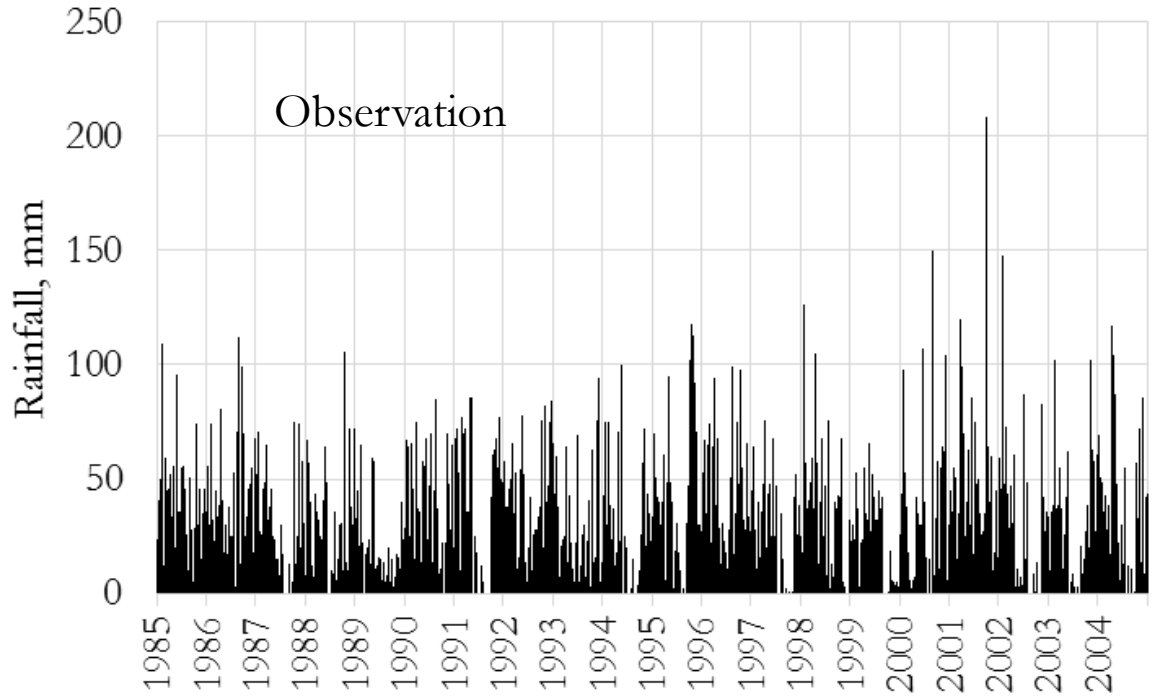

$$x_{GCM_{Future_corrected}} = x_{GCM_{Future}} \frac{F_{obs}^{-1} (F_{GCM_{Future}} (x_{GCM_{Future}}))}{F_{GCM_{Present}}^{-1} (F_{GCM_{Future}} (x_{GCM_{Future}}))}$$

Results: Frequency correction

Results: Intensity correction

Results

Comparison of current (observation) and future bias corrected GCM daily rainfall over Jakarta region

- ▶ Significantly higher peaks in GCM data
- ▶ Frequent and intense rainfall

Results

Comparison of current (observation) and future bias corrected GCM daily rainfall over Jakarta

Return period, yrs	Present	Future	Increase (%)
2	155	161	3
5	178	200	12
10	195	230	18
20	212	261	23
50	234	300	28

Conclusive remarks

- ▶ Haphazard Urbanization and Climate Change are the greatest challenges for urban flood disaster risk reduction.
- ▶ The climate projections revealed **significant increase in rainfall magnitude (intensity)** for a range of durations and return periods.
- ▶ The increase in rainfall intensity and magnitude has major implications on ways in which current (and future) municipal wastewater management infrastructure is designed, operated, and maintained.
- ▶ The **design standards and guidelines** currently employed **needs to be reviewed** in the lights of the results of this research **to reflect the impacts of climatic change.**
- ▶ Flexible adaptive measures should be mainstreamed.
