The MIT-NCER Used Electronics Flows Report is available for media preview online at <http://bit.ly/1eqsOrm>

World E-Waste Map Reveals National Volumes, International Flows

***Volume of end-of-life electronics worldwide expected to jump
one-third
to 65.4 million tonnes annually by 2017***

***New report details US generation and destinations of shipments
of used electronics no longer residing in households;
methodology offers world guide***

By 2017, all of that year's end-of-life refrigerators, TVs, mobile phones, computers, monitors, e-toys and other products with a battery or electrical cord worldwide could fill a line of 40-ton trucks end-to-end on a highway straddling three quarters of the Equator.

That startling forecast, based on data compiled by “Solving the E-Waste Problem (StEP Initiative)” — a partnership of UN organizations, industry, governments, non-government and science organizations— represents a global jump of 33% in just five years.

While most of these used e-products are destined for disposal, gradually improving efforts in some regions are diverting some of it to recycling and reuse.

The escalating global e-waste problem is graphically portrayed in a first-of-its-kind StEP E-Waste World Map, available online at www.step-initiative.org/index.php/WorldMap.html,

The map was launched coincident with a complementary new StEP report characterizing US domestic and transboundary flows of used electronics no longer residing in households, detailed below.

The interactive map resource, presenting comparable annual data from 184 countries, shows the estimated amount of electrical and electronic equipment (EEE — anything with a battery or a cord) put on the market and how much resulting e-waste is eventually generated (i.e. comes out of use or post-use storage destined for collection by a recycling company or disposal).

By providing a better sense of e-waste quantities to anticipate, the initiative is expected to help governments and companies plan e-waste management.

The map shows, for example, that almost 48.9 million metric tons of used electrical and electronic products was produced last year — an average of 7 kg (43 pounds - comparable to eight red clay bricks) for each of the world’s 7 billion people.

And the flood of e-waste is growing. Based on current trends, StEP experts predict that, by 2017, the total annual volume will be 33 per cent higher at 65.4 million tons, the weight equivalent of almost 200 Empire State Buildings or 11 Great Pyramids of Giza.

“Although there is ample information about the negative environmental and health impacts of primitive e-waste recycling methods, the lack of comprehensive data has made it hard to grasp the full magnitude of the problem,” says Ruediger Kuehr of United Nations University and Executive Secretary of the StEP Initiative,

“We believe that this constantly updated, map-linked database showing e-waste volume by country together with legal texts will help lead to better awareness and policy making at the public and private levels.”

The StEP e-waste world map database shows that in 2012 China and the United States topped the world’s totals in market volume of EEE and e-waste. China put the highest volume of EEE on the market in 2012 – 11.1 million tons, followed by the US at 10 million tons.

Those positions were reversed when it came to the total volume of e-waste generated per year, there being more products put on the market in the past in the US which are now likely to be retired. Here the US had the world’s highest figure of 9.4 million tons and China generated the second highest e-waste total of 7.3 million tons.

However, the world’s two biggest economies were far apart when it came to the amount of annually e-waste per person. Here the US was highest among major countries (and seventh overall) with each American responsible for an average 29.8 kg of hi-tech trash. That was almost six times higher than China’s per capita figure of 5.4 kg.

Information covering e-waste rules, regulations, policies and guidance is also available via the StEP e-waste map. This is obtained substantially from StEP member Compliance & Risks’ knowledge management platform, C2P, and highlights the huge variety of requirements and lack of consistency in tackling the e-waste issue throughout the world.

Report offers detailed US analysis

A report released in tandem with the map was developed by the Massachusetts Institute of Technology (MIT) Materials Systems Laboratory and the US National Center for Electronics Recycling (NCER), and funded by the US Environmental Protection Agency in support of the US government’s National Strategy for Electronics Stewardship.

The detailed analysis of the United States’ generation, collection and export of some types of used electronics shows that about 258.2 million used, whole unit computers, monitors, TVs and mobile phones were generated in 2010.

The study, *Quantitative Characterization of Domestic and Transboundary Flows of Used Electronics*, found mobile phones constitute the biggest component in units – with an estimated 120 million collected – while TVs and computer monitors made up a major proportion of the total weight.

Despite growing interest and concern surrounding transboundary movements of used electronics around the world, there is a dearth of data on their movements. Although a multitude of different data sources exist, coherent sets of information on used electronics leaving households and their movement are lacking because of inherent challenges in obtaining such information, both the StEP e-waste world map and the MIT/NCER study are addressing.

These challenges include limited mechanisms for data collection, undifferentiated trade codes, lack of consistent definitions for categorizing and labelling used electronics as well as their components, minimal regulatory oversight, and limited agreement on the definitions of end uses (i.e., reuse vs. recycling and shipments for repair vs. recycling).

Two-thirds of the used units (56 percent of total weight) were collected for reuse or recycling and 8.5 per cent of the collected units (3.1 percent of total weight) were exported as whole units. This export figure, based on trade data, likely represents the low end of the range as not all whole units may be shipped using appropriate trade codes. Researchers say disassembled products could have been shipped separately but were not tracked (adding that disassembled products are of less international concern than products likely to be disassembled in developing countries).

The research shows that most larger electronic items, especially TVs and monitors, were exported overland or by sea to destinations such as Mexico, Venezuela, Paraguay and China while used computers, especially laptops, were more likely to go to Asian countries such as Hong Kong, United Arab Emirates and Lebanon.

The main destinations for mobile phones were Hong Kong and countries in Latin America and the Caribbean such as Paraguay, Guatemala, Panama, Peru and Colombia.

“An advantage of the trade data approach is that it tracks the destinations of shipped products,” says report co-author Randolph Kirchain of MIT. “However, the destination in the trade data may be an initial stopping point. Re-exports and final destinations are not always reported in trade data.”

“If it is a stopping point before re-export, the final destination is likely in the same region.”

The report underlines great ongoing challenges in related intelligence gathering worldwide, such as a lack of consistent definitions for categorizing and labeling used electronics and

their components, minimal regulatory oversight, and limited agreement on the definitions of end uses (i.e., reuse vs. recycling). Among several recommendations:

- Create trade codes for used electronic products to enable better tracking and distinction of shipments for example only for repair.
- More open access to shipment level trade data to enable more accurate analyses of export flows
- Greater reporting of re-export destinations to improve the accuracy of final destinations
- Track flows over multiple years to discern trends

Solving the E-waste Problem fosters inclusive solutions-oriented dialogue, cooperation and consensus by providing a global platform for sharing information, knowledge and recommendations founded on expert scientific research and members' experiences.

The initiative works internationally with receptive external partners to develop fair and objective policies to stimulate and demonstrate practical, measured and effective responses to e-waste prevention, management and processes and leads the e-waste management discussion worldwide by providing a scientific basis from which to inform and actively change the awareness, knowledge, attitudes and behavior of the international business and consumer public.

Quotable quotes

Kazuhiko Takeuchi, UN Assistant Secretary General and Senior Vice-Rector, UNU

“As global think tank the mission of the United Nations University (UNU) is to contribute, through collaborative research and education, to efforts to resolve the pressing global problems of human survival, development and welfare that are the concern of the United Nations, its peoples and member states. The e-waste challenge is among these problems and UNU is committed through its research and also through coordinating the Solving the E-waste Problem (StEP) Initiative to provide science-based but applied recommendations to policy makers in governments and industry. And knowing and understanding the magnitude of the issue is key.”

Jane Nishida, Acting Assistant Administrator, US-EPA Office of International and Tribal Affairs

“EPA partnered with the United Nations University’s Solving the E-waste Problem (StEP) Initiative understanding that the growing e-waste problem can only be addressed effectively

when we have better information on the global flows of used electronics. We are pleased that StEP, working with the Massachusetts Institute of Technology and the National Center for Electronics Recycling, was able to deliver a report that provides a scientific-based approach to generating information on US exports of used electronics.”

Jason Linnell, Executive Director, National Center for Electronics Recycling (NCER)

"The release of this study in the US is key to understanding one piece of the puzzle about exports of used electronics. The research also shows substantial increases in the US in collecting used electronics, and will set a baseline to measure future progress."

Joel Clark, Professor of Materials Systems and Engineering Systems, Founder of the Materials Systems Laboratory, Massachusetts Institute of Technology

“We cannot possibly manage complex, transboundary e-waste flows until we have a better understanding of the quantities involved and the destinations. This research is an important first step in that direction.”

United Nations University

(unu.edu)

UNU is an autonomous organ of the UN General Assembly dedicated to generating and transferring knowledge and strengthening capacities relevant to global issues of human security, development, and welfare. The University operates through a worldwide network of research and training centres and programmes, coordinated by UNU Centre in Tokyo.

StEP

(step-initiative.org)

Solving the E-Waste Problem is a partnership of several UN organizations, prominent industry, government and international organizations, NGOs and the science sector. StEP initiates and facilitates sustainable e-waste handling through analysis, planning and pilot projects.

The Materials Systems Laboratory at the Massachusetts Institute of Technology

(msl.mit.edu)

The Materials Systems Laboratory (MSL) is an interdisciplinary research group that studies the strategic implications of materials and materials processing choices by modeling the economic and environmental consequences of engineering decisions. It resides within the Department of Materials Science & Engineering and the Engineering Systems Division at MIT and maintains affiliations with a number of labs, centers and programs at the Institute. MSL works jointly with numerous corporate, government, academic and industrial consortia as research partners on a wide variety of research areas including automotive lightweighting, electronics recycling, resource scarcity, and product and process environmental footprinting.

About the National Center for Electronics Recycling (NCER):

(electronicsrecycling.org)

The NCER is a 501 (c)(3) non-profit organization based in Parkersburg, West Virginia that is dedicated to the development and enhancement of a national infrastructure for the recycling of used electronics in the U.S. The NCER develops research and program. targeting the recycling of used electronics in the United States, participation in pilot projects to advance and encourage electronics

recycling, and the development of programs that reduce the burden of government through private management of electronics recycling systems.

About the US Environmental Protection Agency (EPA)

(epa.gov)

EPA is a US federal government agency created for the purpose of protecting human health and the environment. EPA has its headquarters in Washington, D.C. and 10 regional offices throughout the United States.
